Cheat Sheet: API's and Data Collection

Package/Method	Description	Code Example
Accessing element attribute	Access the value of a specific attribute of an HTML element.	<pre>Syntax: 1 attribute = element[(attribute)] Example: 1 href = link_element[(href)]</pre>
BeautifulSoup()	Parse the HTML content of a web page using BeautifulSoup. The parser type can vary based on the project.	<pre>Syntax: 1 soup = BeautifulSoup(html, (html.parser)) Example: 1 html = (https://api.example.com/data) soup = BeautifulSoup(html, (html.parser))</pre>
delete()	Send a DELETE request to remove data or a resource from the server. DELETE requests delete a specified resource on the server.	<pre>Syntax: 1 response = requests.delete(url) Example: 1 response = requests.delete((https://api.example.com/delete))</pre>
find()	Find the first HTML element that matches the specified tag and attributes.	<pre>Syntax: 1 element = soup.find(tag, attrs) Example: 1 first_link = soup.find((a), {(class): (link)})</pre>
find_all()	Find all HTML elements that match the specified tag and attributes.	<pre>Syntax: 1 elements = soup.find_all(tag, attrs) Example: 1 all_links = soup.find_all((a), {(class): (link)})</pre>
findChildren()	Find all child elements of an HTML element.	<pre>Syntax:</pre>
get()	Perform a GET request to retrieve data from a specified URL. GET requests are typically used for reading data from an API. The response variable will contain the server's	<pre>Syntax:</pre>

Headers	response, which you can process further. Include custom headers in the request. Headers can provide additional information to the server, 1 base_url = (https://api.example.com/data) headers = {(Authorization): (Bearer YOUR_TOKEN)} response Total Company
	such as authentication tokens or content types.
Import Libraries	Import the necessary Python 1 from bs4 import BeautifulSoup libraries for web scraping.
json()	Parse JSON data from the response. This extracts and works with the data returned by the API. The response.json() method converts the JSON response into a Python data structure (usually a dictionary or list). Syntax: 1
next_sibling()	Syntax: 1 sibling = element.find_next_sibling() Example: 1 sibling = element.find_next_sibling() Example: 1 next_sibling = current_element.find_next_sibling()
parent	Syntax: Access the parent element.parent element in the Document Object Model (DOM). Syntax: 1 parent = element.parent Example: Example: 1 parent_div = paragraph.parent
post()	Send a POST request to a specified URL with data. Create or update POST requests using resources on the server. The data parameter contains the data to send to the server, often in JSON format. Syntax: 1

```
Send a PUT
                    request to
                    update data
                    on the server.
                    PUT requests
                                     Syntax:
                    are used to
                                        1
                                              response = requests.put(url, data)
                    update an
                    existing
put()
                                     Example:
                    resource on
                    the server with
                                              response = requests.put((https://api.example.com/update), data={(key): (value)})
                    the data
                    provided in
                    the data
                    parameter,
                    typically in
                    JSON format.
                    Pass query
                                     Syntax:
                    parameters in
                    the URL to
                                              params = {(param_name): (value)}
                    filter or
                    customize the
                                     Example:
Query
                    request. Query
parameters
                    parameters
                                              base_url = "https://api.example.com/data"
                                        1
                    specify
                                        2
                                              params = {"page": 1, "per_page": 10}
                    conditions or
                    limits for the
                                        3
                                              response = requests.get(base_url, params=params)
                    requested
                    data.
                                     Syntax:
                                        1
                                              element = soup.select(selector)
                    Select HTML
                    elements from
select()
                    the parsed
                                     Example:
                    HTML using a
                    CSS selector.
                                              titles = soup.select((h1))
                    Check the
                    HTTP status
                    code of the
                    response. The
                                     Syntax:
                    HTTP status
                    code indicates
                                              response.status_code
                    the result of
                    the request
                                     Example:
                    (success, error,
status code
                    redirection).
                                              url = "https://api.example.com/data"
                                        1
                    Use the HTTP
                                        2
                                              response = requests.get(url)
                    status codelt
                                        3
                                              status_code = response.status_code
                    can be used
                    for error
                    handling and
                    decision-
                    making in your
                    code.
                                     Tag Example:
                    Specify any
                                         1
                                               - (a): Find anchor () tags.
                    valid HTML
                                               - (p): Find paragraph ((p)) tags.
                                         2
                    tag as the tag
                                         3
                                               - (h1), (h2), (h3), (h4), (h5), (h6): Find heading tags from level 1 to 6 ( (h1),n (h2)).
                    parameter to
                    search for
                                         4
                                               - (table): Find table () tags.
                    elements of
                                         5
                                               - (tr): Find table row () tags.
tags for find()
                    that type. Here
and find all()
                                         6
                                               - (td): Find table cell ((td)) tags.
                    are some
                                         7
                                               - (th): Find table header cell ((td))tags.
                    common
                    HTML tags
                                         8
                                               - (img): Find image ((img)) tags.
                    that you can
                                         9
                                               - (form): Find form ((form)) tags.
                    use with the
                                               - (button): Find button ((button)) tags.
                                        10
                    tag parameter.
```

Retrieve the text content of an HTML element.	Syntax: 1 text = element.text Example: 1 title_text = title_element.text
